

After 140 min of turning off the light source, the temperature of the bottom surface of the sample was still 10 °C higher than that before the test. This shows that after the light source is turned off, the energy absorbed by ODE is released through the solid-liquid phase change. This favors continuous evaporation on cloudy days or nights.

The RTE is a parameter that evaluates the amount of energy that is lost in the storage process, in energy storage devices. It can be determined by: $RTE = (V_1 / V_0) \times 100$, being V_1 the potential of the discharge plateau and V_0 the potential of the charge plateau. Both these points are indicated in Figure 2F.

As described in their earlier publication, the solvent used in their freeze-casting approach is a chemical called camphene, which produces tree-like dendritic structures when frozen. Other types of pore distributions can also be obtained by using different solvents. To test the samples, the team constructed "sandwich-type" two-electrode supercapacitors and ...

Novel 3D-structured film architectures were introduced on a fluorine-doped tin oxide (FTO)/glass substrate using a micro 3D-printing method with an automatic x/y/z-axis control system for ultrafast EC energy storage devices. The 3D-structured film architecture featured a grid pattern of uniform micro-intersections of micro-wide VO with ...
