The core element of a flywheel consists of a rotating mass, typically axisymmetric, which stores rotary kinetic energy E according to (Equation 1) $E = \frac{1}{2} I \omega^2$ [J], where E is the stored kinetic energy, I is the flywheel moment of inertia [kgm²], and ω is the angular speed [rad/s]. In order to facilitate storage and extraction of electrical energy, the rotor ...

The minimum speed of the flywheel is typically half its full speed, the storage energy is be given by $\frac{1}{2} I \omega_f^2$ where I is the rotor moment of inertia in kgm² and the ω_f maximum rotational speed in rad/s. The power level is controlled by the size of the M/G, so this is independent of the rotor.
