

Picture of the solar system with asteroid belt

What is the asteroid belt?

The asteroid belt is between the orbits of Mars and Jupiter, spanning approximately 2.1 to 3.3 astronomical units (AU) from the Sun (1 AU is the average distance from the Earth to the Sun). This zone marks a significant division between the inner, rocky planets and the outer gas giants of our solar system.

How did the asteroid belt form?

The prevailing theory suggests that the asteroid belt formed from the solar nebula, the same cloud of gas and dust that created the Sun and planets. Gravitational disturbances from Jupiter prevented these objects from coalescing into a planet, leaving them as remnants of the early solar system. Discarded Theories:

Does the asteroid belt reach Earth's orbit?

It doesn't quite reach Earth's orbit. Image via NASA. Bottom line: The asteroid belt is a region of our solar system - between the orbits of Mars and Jupiter - where many small bodies orbit our sun. Andy Briggs has spent the past 30 years communicating astronomy, astrophysics and information technology to people.

How many craters are in the asteroid belt?

The set of 3 craters known as the snowman are at the top left. Image via NASA. We often call the asteroid belt the main belt to distinguish it from other, smaller groups of asteroids in the solar system such as the Lagrangians and Centaurs in the outer solar system.

Which asteroid belt is closest to Jupiter?

Comparison of the Oort cloud, Kuiper Belt and the Main Asteroid Belt. The asteroids of the inner Solar System and Jupiter: The main asteroid belt is located between the orbits of Jupiter and Mars. Known objects in the Kuiper belt beyond the orbit of Neptune. (Scale in AU; epoch as of January 2015.)

Who discovered the asteroid belt?

The asteroid belt's discovery began when astronomers were searching for a "missing planet" between Mars and Jupiter. 1596: Johannes Kepler predicted the location of a planet between Mars and Jupiter. 1766: Johann Titius noted a pattern in the location of planetary orbits, leading to the formation of the Titius-Bode Law.

The asteroid belt is huge and the space between each of the asteroids is over 600,000 miles. The circumference of Earth is only 24,901.45 miles, which means that the distance between objects in the asteroid belt is more than 24 times the circumference of Earth. Interesting Facts About The Asteroid Belt. The asteroid belt was first discovered in ...

Solar System Home; Explore This Section Asteroids Multimedia. Filters ... NASA's Psyche Spacecraft Prepares for Trip to Asteroid by Testing Solar Arrays. ... Planets. Asteroids, Comets & Meteors. Kuiper Belt.

Return to top. National Aeronautics and Space Administration. NASA explores the unknown in air and space, innovates for the benefit of ...

The detection of this asteroid -- which the team suspects to be the smallest observed to date by Webb and one of the smallest detected in the main belt -- would, if confirmed as a new asteroid discovery, have important implications for our understanding of the formation and evolution of the solar system.

The Solar System . The Sun; Mercury; Venus; Earth; The Moon; Mars; Jupiter; Saturn; Uranus; Neptune; ... This collage of radar images of near-Earth asteroid 1999 JD6 was collected by NASA scientists on July 25, 2015. ... depicts asteroid Psyche, which lies in the main asteroid belt between Mars and Jupiter. The streak circled in the center of ...

Overview Asteroids, sometimes called minor planets, are rocky, airless remnants left over from the early formation of our solar system about 4.6 billion years ago. Most asteroids can be found orbiting the Sun between Mars and Jupiter within the main asteroid belt. Asteroids range in size from Vesta - the largest at about 329 miles [...]

Ahuna Mons is also evidence of recent geological activity (within the past 100 million years or less), making Ceres one of a few bodies in the solar system that show signs of recent activity. Hubble's images showed evidence of several brighter areas on Ceres' surface.

Ceres is the largest object in the asteroid belt between Mars and Jupiter, and it's the only dwarf planet located in the inner solar system. Like Pluto, Ceres also was once classified as a planet. Ceres was the first dwarf planet to be visited by a spacecraft - NASA's Dawn mission.

The asteroid and comet belts orbit the Sun from the inner rocky planets into outer parts of the Solar System, interstellar space. [16] [17] [18] An astronomical unit, or AU, is the distance from Earth to the Sun, which is approximately 150 billion meters (93 million miles). [19] Small Solar System objects are classified by their orbits: [20] [21]. Main Asteroid belt (main belt), between ...

Astronomers used NASA's James Webb Space Telescope to image the warm dust around a nearby young star, Fomalhaut, in order to study the first asteroid belt ever seen outside of our solar system in infrared light. But to their surprise, the dusty structures are much more complex than the asteroid and Kuiper dust belts of our solar system.

Similarly, inside our solar system Jupiter corrals the asteroid belt, the inner edge of the Kuiper Belt is sculpted by Neptune, and the outer edge could be shepherded by as-yet-unseen bodies beyond it. As Webb images more systems, ...

The biggest objects in the asteroid belt are the dwarf planet Ceres and the three asteroids named Vesta, Pallas, and Hygiea. Ceres is the only asteroid from the asteroid belt categorized as a dwarf planet, and it is the most prominent asteroid in the inner Solar System. The Asteroid Belt is approximately 2.2 to 3.2 Astronomical Units from the Sun.

Using the European Southern Observatory's Very Large Telescope (ESO's VLT) in Chile, astronomers have imaged 42 of the largest objects in the asteroid belt, located between Mars and Jupiter. Never before had such a large group of asteroids been imaged so sharply. The observations reveal a wide range of peculiar shapes, from spherical to dog-bone, and are ...
