Where "p" is the density of water, "g" is the acceleration due to gravity, "h" is the height drop, and "?" is the efficiency of the turbines/pumps. Calculating the volume of water required for pumped storage involves considering factors such as the height difference between the reservoirs, the efficiency of the pump and turbine, and the desired energy output.

After that, the high-temperature HTM will transfer heat to the working fluid in the heat exchanger and augment the temperature and pressure of the working fluid. Then the high-temperature and high-pressure working fluid drives the turbine to generate electric power. This is the working principle of a typical CSP system.

A hydraulic accumulator is a pressure vessel containing a membrane or piston that confines and compresses an inert gas (typically nitrogen). Hydraulic fluid is held on other side of the membrane. An accumulator in a hydraulic device stores hydraulic energy much like a car battery stores electrical energy.
